

Historical Retention Case Notes

Case 2024-0113

Subscriber flagged with auto-renew off and no listening activity in 60+ days (dormant + non-renewing). Content-led win-back message alone did not produce a return session over two weeks. Escalated to a combined offer: one month free plus a renewal reminder. Subscriber returned and re-enabled auto-renew. Note: the dormant signal here was the dominant blocker - the auto-renew reminder alone (without addressing dormancy first) had previously failed on a similar profile earlier the same quarter.

Case 2024-0187

Subscriber on a heavily discounted plan (actual_amount_paid roughly 40% of plan_list_price) cancelled in the exact cycle the discount expired, consistent with the discount-expiry pattern. A stepped-down discount (25% instead of the original 40%, rather than a flat re-offer of the original rate) was tested on a similar profile the following month and retained the subscriber at a smaller ongoing discount rather than the full original rate.

Case 2024-0249

Subscriber showed a negative activity_trend for three consecutive weeks with active_days_30 still in a normal range - engagement was falling but not yet low enough to look dormant. A single lightweight recommendation refresh prompt was sent (Playbook P6 style, not a full win-back). Activity_trend recovered to flat the following month without further contact, suggesting the early, low-intensity touch was sufficient and a heavier win-back campaign would have been unnecessary spend.

Case 2024-0301

Subscriber on a 30-day plan with high completion_ratio and good active_days_30 (clearly engaged) still churned at a renewal boundary. Post-hoc review found no dormancy or price signal - the account had simply never been offered a longer plan and cancelled after a short lapse in remembering to renew manually. This case motivated adding the plan-commitment upsell (Playbook P2) as a proactive offer at the first renewal for new short-cycle subscribers, rather than waiting for an at-risk signal to appear.
